

Document routing decides which extraction pipeline a file deserves. A converter that ignores page geometry will interleave columns of text. The probe reads the file header instead of trusting the extension. Layout is measured per horizontal band, not from the page as a whole. A scanned page carries no text layer and must be rendered as an image. Structure is lost when a layout-aware reader is replaced by a naive one. Magic bytes are authoritative because extensions are frequently wrong. Every decision here is deterministic, offline, and free of model calls. The gutter between columns is found by merging text intervals per band. Superscripts, italics and headings survive a layout-aware conversion. A single reference page must not outvote multi-column body pages. The correct pipeline for a two-column paper is the layout-aware one.
